

# Caramasa

The **Caramasa** Cu-porphyry exploration project is located in Northern Chile. Erosion in a river canyon exposes a Monzodioritic intrusive with porphyry-style alteration that could relate to a target located under cover to the North or South of the canyon. A single profile of MT data defines a stockwork as a strongly anomalous high resistivity feature in the central part of the survey line.

## Lithology

-  Monzo-Dioritic Intrusive
-  Aplitic Intrusive
-  Quartz-Tm Breccia
-  Ignimbrite Cover (Post Mx)

## Alteration

-  Hematitic
-  Phyllic
-  Propylitic
